`object`

fitted model: estimates and conditional draws of S

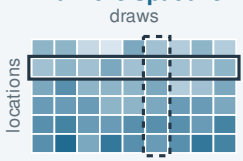
`newdata`

prediction locations and covariates

`boundaries`

polygons (optional)

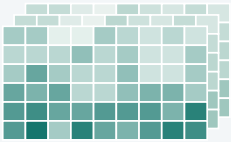
1 Draw the spatial effect



`type = "marginal"`
each row (one location) has the right distribution

`type = "joint"`
each column (one draw) is also one possible map

2 Build the targets in every draw



linear predictor = fixed effects + spatial draw

`include` adds a nugget or random effects

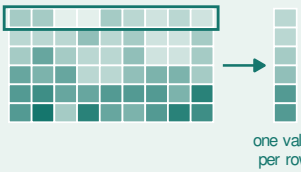
prevalence or rate = its inverse link

`transform` adds further targets

each target has the same rows and columns

3 Summarise each location

across its draws



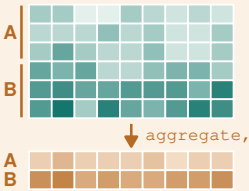
mean, interval width, exceedance, ...

set by `summaries, thresholds, level`

`$predictions`

4 Aggregate within each draw

then summarise each polygon



one value per polygon in each draw

then summarise each row as in step 3

needs joint draws, chosen automatically

`$boundary_summary`

`parameter_uncertainty = TRUE`

repeats steps 1 and 2 for each parameter draw and pools all draws
